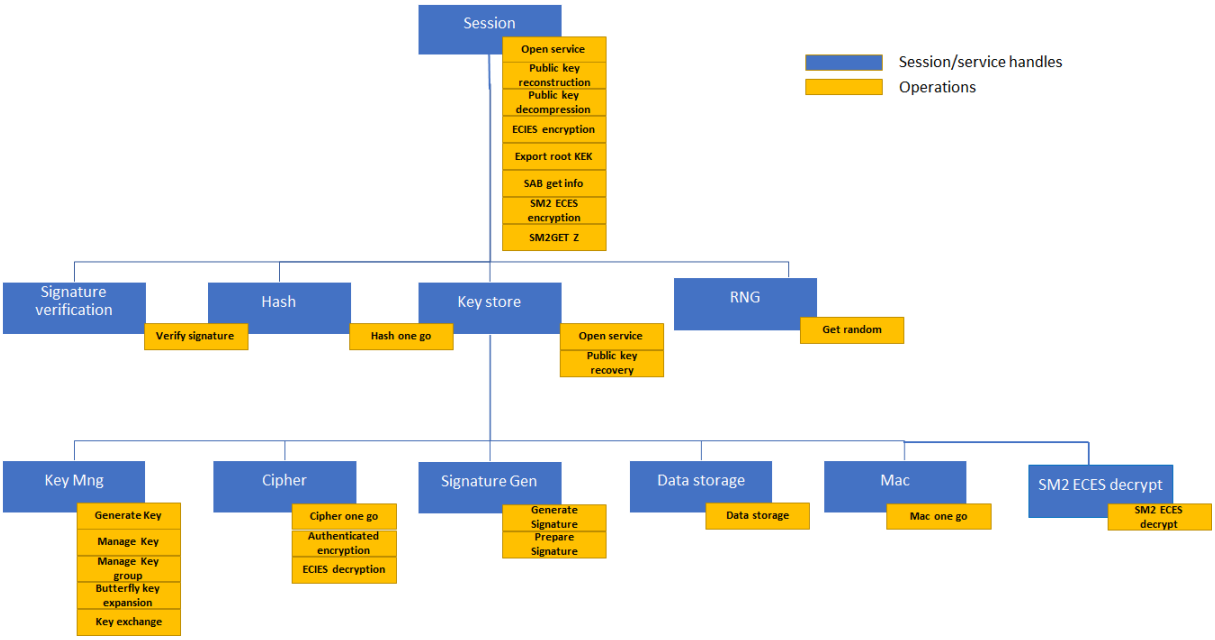
3 General concepts related to the API



3.1 Session

The API must be initialized by a potential requestor by opening a session.
The session establishes a route (MU, DomainID...) between the requester and the HSM. When a session is opened, the HSM returns a handle identifying the session to the requester.

3.2 Service flow

For a given category of services, the requestor is expected to open a service flow by invoking the appropriate HSM API.
The session handle, as well as the control data needed for the service flow, are provided as parameters of the call.
Upon reception of the open request, the HSM allocates a context in which the session handle, as well as the provided control parameters are stored and return a handle identifying the service flow.
The context is preserved until the service flow, or the session, are closed by the user and it is used by the HSM to proceed with the sub-sequent operations requested by the user on the service flow.

3.3 Example

```
/* Open a session: create a route between the user and the HSM */
hsm_open_session(&open_session_args, &session_hdl);

/* Open a key store - user is authenticated */
hsm_open_key_store_service(session_hdl, &open_svc_key_store_args, &key_store_hdl);
/* Open hash service - it grants access to hashing operations */
hsm_open_hash_service (session_hdl, &open_svc_hash_args, &hash_hdl);
/* Open cipher service - it grants access to ciphering operations */
hsm_open_cipher_service(key_store_hdl, &open_svc_cipher_args, &cipher_hdl);

/* Perform AES ECB, CCB ... */
hsm_cipher_one_go (cipher_hdl, &op_cipher_one_go_args);
/* Perform authenticate and encryption algos: e.g AES GCM */
hsm_auth_enc (cipher_hdl, &op_auth_enc_args);
/* Perform hashing operations: e.g SHA */
hsm_hash_one_go (hash_hdl, &op_hash_one_go_args);

/* Close the session and all the related services */
hsm_close_session(session_hdl);
```

3.4 Key store

A key store can be created by specifying the CREATE flag in the hsm_open_key_store_service API. Please note that the created key store will be not stored in the NVM till a key is generated/imported specyfing the "STRICT OPERATION" flag.
Only symmetric and private keys are stored into the key store. Public keys can be exported during the key pair generation operation or recalculated through the hsm_pub_key_recovery API.
Secret keys cannot be exported under any circumstances, while they can be imported in encrypted form.

3.4.1 Key management

Keys are divided in groups, keys belonging to the same group are written/read from the NVM as a monolitic block.
Up to 3 key groups can be handled in the HSM local memory (those immediatly available to perform crypto operations), while up to 1000 key groups can be handled in the external NVM and imported in the local memory as needed.
If the local memory is full (3 key groups already reside in the HSM local memory) and a new key group is needed by an incoming user request, the HSM swaps one of the local key group with the one needed by the user request.
The user can control which key group must be kept in the local memory (cached) through the manage_key_group API lock/unlock mechanism.
As general concept, frequently used keys should be kept, when possible, in the same key group and locked in the local memory for performance optimization.

3.4.2 NVM writing

All the APIs modyfing the content of the key store (key generation, key_management, key derivation functions) provide a "STRICT OPERATION" flag. If the flag is set, the HSM triggers and export of the encrypted key group into the external NVM and increments (blows one bit) the OTP monotonic counter used as roll back protection. Please note that the "STRICT OPERATION" has effect only on the current key group.
Any update to the key store must be considered as effective only after an operation specifing the flag "STRICT O↩ PERATION" is aknowledged by the HSM. All the operations not specifying the "STRICT OPERATION" flags impact the HSM local memory only and will be lost in case of system reset
Due to the limited monotonic counter size (QXPB0 up to 1620 update available by default), the user should, when possible, perform multiple udates before setting the "STRICT OPERATION" flag (i.e. keys to be updated should be kept in the same key group).
Once the monotonic counter is completely blown a warning is returned on each update operation to inform the user that the new updates are not roll-back protected.

- typedef uint8_t **hsm_svc_key_store_flags_t**

Functions

- hsm_err_t hsm_open_key_store_service (hsm_hdl_t session_hdl, open_svc_key_store_args_t *args, hsm_hdl_t *key_store_hdl)
- hsm_err_t hsm_close_key_store_service (hsm_hdl_t key_store_hdl)

5.3.1 Detailed Description

User must open a key store service flow in order to perform the following operations:

- create a new key store
- perform operations involving keys stored in the key store (ciphering, signature generation...)
- perform a key store reprovisioning using a signed message. A key store re-provisioning results in erasing all the key stores handled by the HSM.

To grant access to the key store, the caller is authenticated against the domain ID (DID) and Messaging Unit used at the keystore creation, additionally an authentication nonce can be provided.

Data Fields

5.3.2 Data Structure Documentation

5.3.2.1 struct open_svc_key_store_args_t

Data Fields

uint32_t	key_store_identifier	user defined id identifying the key store. Only one key store service can be opened on a given key_store_identifier.
uint32_t	authentication_nonce	user defined nonce used as authentication proof for accesing the key store.
uint16_t	max_updates_number	maximum number of updates authorized for the key store. Valid only for create operation. This parameter has the goal to limit the occupation of the monotonic counter used as anti-rollback protection. If the maximum number of updates is reached, HSM still allows key store updates but without updating the monotonic counter giving the opportunity for rollback attacks.
hsm_svc_key_store_↩ flags_t	flags	bitmap specifying the services properties.
uint8_t	reserved	it must be 0.
uint8_t *	signed_message	pointer to signed_message to be sent only in case of key store re-provisioning
uint16_t	signed_msg_size	size of the signed_message to be sent only in case of key store re-provisioning
uint8_t	reserved_1[2]

5.3.3.2 hsm_err_t hsm_close_key_store_service (hsm_hdl_t *key_store_hdl*)

Close a previously opened key store service flow. The key store is deleted from the HSM local memory, any update not written in the NVM is lost

Parameters

5.4.3 Function Documentation

5.4.3.1 hsm_err_t hsm_open_key_management_service (hsm_hdl_t *key_store_hdl,* open_svc_key_management_↩ args_t * *args,* hsm_hdl_t * *key_management_hdl*)

Open a key management service flow
User must open this service flow in order to perform operation on the key store keys (generate, update, delete)

Parameters

key_store_hdl	handle identifying the key store service flow.
args	pointer to the structure containing the function arguments.
key_management_hdl	pointer to where the key management service flow handle must be written.

Returns

error_code error code.

5.4.3.2 hsm_err_t hsm_generate_key (hsm_hdl_t *key_management_hdl,* op_generate_key_args_t * *args*)

Generate a key or a key pair. Only the confidential keys (symmetric and private keys) are stored in the internal key store, while the non-confidential keys (public key) are exported.
The generated key can be stored using a new or existing key identifier with the restriction that an existing key can be replaced only by a key of the same type.
User can call this function only after having opened a key management service flow.

Parameters

key_management_hdl	handle identifying the key management service flow.
args	pointer to the structure containing the function arguments.

Returns

error code

5.4.3.3 hsm_err_t hsm_manage_key (hsm_hdl_t *key_management_hdl,* op_manage_key_args_t * *args*)

This command is designed to perform the following operations:

- import a key creating a new key identifier (import and create)
- import a key using an existing key identifier (import and update)
- delete an existing key

The key encryption key (KEK) can be previously pre-shared or stored in the key store.

The key to be imported must be encrypted by using the KEK as following:

- Algorithm: AES GCM
- Key: root KEK
- AAD = 0
- IV = 12 bytes
- Tag = 16 bytes
- Plaintext: key to be imported

User can call this function only after having opened a key management service flow

Parameters

key_management_hdl	handle identifying the key management service flow.
args	pointer to the structure containing the function arguments.

Returns

error code

5.4.3.4 hsm_err_t hsm_manage_key_group (hsm_hdl_t *key_management_hdl,* op_manage_key_group_args_t * *args*)

This command is designed to perform the following operations:

- lock/unlock down a key group in the HSM local memory so that the keys are available to the HSM without additional latency
- un-lock a key group. HSM may export the key group into the external NVM to free up local memory as needed
- delete an existing key group

User can call this function only after having opened a key management service flow.

Parameters

key_management_hdl	handle identifying the key management service flow.
args	pointer to the structure containing the function arguments.

Returns

error code

5.4.3.5 hsm_err_t hsm_butterfly_key_expansion (hsm_hdl_t *key_management_hdl,* op_butt_key_exp_args_t * *args*)

This command is designed to perform the butterfly key expansion operation on an ECC private key in case of implicit and explicit certificates. Optionally the resulting public key is exported.
The result of the key expansion function f_k is calculated outside the HSM and passed as input. The expansion function is defined as f_k = f_k_int mod l , where l is the order of the group of points on the curve.
User can call this function only after having opened a key management service flow.

Explicit certificates:

- f_k = expansion function value

out_key = Key + f_k

Implicit certificates:

- f_k = expansion function value,
- hash = hash value used in the derivation of the pseudonym ECC key,
- pr_v = private reconstruction value

out_key = (Key + f_k)∗hash + pr_v

Parameters

key_management_hdl	handle identifying the key store management service flow.
args	pointer to the structure containing the function arguments.

Returns

error code

5.4.3.6 hsm_err_t hsm_close_key_management_service (hsm_hdl_t *key_management_hdl*)

Parameters

key_management_hdl	handle identifying the key management service flow.

5.21.3 Function Documentation

5.21.3.1 hsm_err_t hsm_key_exchange (hsm_hdl_t *key_management_hdl,* op_key_exchange_args_t * *args*)

This command is designed to to derive a secret key that will be stored in the key store as a new key or as an update of an existing key.
A freshly generated key or an existing key can be used as input for the shared secret calculation.
User can call this function only after having opened a key management service flow.
When using the SHA KDF, only Key Encryption Keys (KEKs) can be generated.
As per as per SP800-56C rev2, the KEK is generated using SHA_256(counter || Z || FixedInput), where:

- counter is a 32 bit value of 1 in big endian format
- Z is the shared secret generated by the DH key-establishment scheme
- FixedInput is the literal 'NXP HSM USER KEY DERIVATION' (27 bytes, no null termination).

In the case of HSM_KE_SCHEME_SM2_FP_256 :

- v2x role is receiver
- only HSM_KDF_ALG_FOR_SM2 is supported
- HSM_OP_KEY_EXCHANGE_FLAGS_USE_EPHEMERAL is not supported
- shared_key_type could only be HSM_KEY_TYPE_SM4_128 or HSM_KEY_TYPE_DSA_SM2_FP_256
  - shared_key info could not be a KEK
  - initiator_public_data_type could only be HSM_KEY_TYPE_DSA_SM2_FP_256
  - ke_input = (x||y) || (xephemeral||yephemeral) of the 2 public keys of initiator
- ke_out = (x||y)|| (xephemeral||yephemeral) of the 2 public keys the receiver
- kdf_input = (Zinitiator||Zinitiator||V1) if HSM_OP_KEY_EXCHANGE_FLAGS_KEY_CONF_EN enabled, where V1 is the verification value calculated on the initiator side
- kdf_output = (VA||VB) if HSM_OP_KEY_EXCHANGE_FLAGS_KEY_CONF_EN enabled, 0 otherwise.
- This SM2 key exchange algorithm is specified in GB/T 32918.

Parameters

key_management_hdl	handle identifying the key store management service flow.
args	pointer to the structure containing the function arguments.
