## 3 General concepts related to the API

### 3.1 Session

The API must be initialized by a potential requestor by opening a session.

The session establishes a route (MU, DomainID...) between the requestor and the HSM. When a session is opened, the HSM returns a handle identifying the session to the requestor.

### 3.2 Service flow

For a given category of services, the requestor is expected to open a service flow by invoking the appropriate HSM API.

The session handle, as well as the control data needed for the service flow, are provided as parameters of the call.

Upon reception of the open request, the HSM allocates a context in which the session handle, as well as the provided control parameters are stored and return a handle identifying the service flow.

The context is preserved until the service flow, or the session, are closed by the user and it is used by the HSM to proceed with the sub-subsequent operations requested by the user on the service flow.

### 3.3 Key store

A key store can be created by specifying the CREATE flag in the `hsm_open_key_store_service` API. Please note that the created key store will be not stored in the NVM till a key is generated/imported specifying the STRICT OPERATION flag.

Only symmetric and private keys are stored into the key store. Public keys can be exported during the key pair generation operation or recalculated through the `hsm_pub_key_recovery` API.

Secret keys cannot be exported under any circumstances, while they can be imported in encrypted form.

#### 3.3.1 Key management

Keys are divided in groups, keys belonging to the same group are written/read from the NVM as a monolithic block. Up to 3 key groups can be handled in the HSM local memory (those immediately available to perform crypto operation), while up to 1024 key groups can be handled in the external NVM and imported in the local memory as needed. If the local memory is full (3 key groups already reside in the HSM local memory) and a new key group is needed by an incoming user request, the HSM swaps one of the local key group with the one needed by the user request. A control of which key group should be kept in the local memory (cached) is provide through the `manage_key_group` API lock/unlock mechanism.

As general concept, frequently used keys should be kept, when possible, in the same key group and locked in the local memory for performance optimization.

#### 3.3.2 NVM writing

All the APIs modifying the content of the key store (key generation/management) provide a "STRICT UPDATE" flag. If the flag is set, the HSM triggers and export of the encrypted key group into the external NVM and blows one bit of the OTP monotonic counter.

Any update to the key store must be considered as effective only after an operation specifying the flag "STRICT UPDATE" is acknowledged by the HSM. All the operations not specifying the "STRICT UPDATE" flags impact the HSM local memory only and will be lost in case of system reset

Due to the limited monotonic counter size (QXPB0 up to 1620 update available), the user should, when possible, perform multiple updates before setting the "STRICT UPDATE" flag.

Once the monotonic counter is completely blown a warning is returned on each update operation to inform the user that the new updates are not roll-back protected.

```
hsm_err_t hsm_generate_key (
    hsm_hdl_t key_management_hdl,
    op_generate_key_args_t * args )
```

Generate a key or a key pair. Only the confidential keys (symmetric and private keys) are stored in the internal key store, while the non-confidential keys (public key) are exported.

The generated key can be stored using a new or existing key identifier with the restriction that an existing key can be replaced only by a key of the same type.

User can call this function only after having opened a key management service flow.

**Parameters**

<i>key_management_hdl</i>	handle identifying the key management service flow.
<i>args</i>	pointer to the structure containing the function arguments.

**Returns**

error code

**6.4.2.3 hsm\_manage\_key()**

```
hsm_err_t hsm_manage_key (
    hsm_hdl_t key_management_hdl,
    op_manage_key_args_t * args )
```

This command is designed to perform the following operations:

- import a key creating a new key identifier
- import a key using an existing key identifier
- delete an existing key

User can call this function only after having opened a key management service flow

    op_manage_key_group_args_t * args )
```

This command is designed to perform the following operations:

- lock/unlock down a key group in the HSM local memory so that the keys are available to the HSM without additional latency
- un-lock a key group. HSM may export the key group into the external NVM to free up local memory as needed
- delete an existing key group

User can call this function only after having opened a key management service flow

## Parameters

<i>key_management_hdl</i>	handle identifying the key management service flow.
<i>args</i>	pointer to the structure containing the function arguments.

```
hsm_err_t hsm_butterfly_key_expansion (
    hsm_hdl_t key_management_hdl,
    op_butt_key_exp_args_t * args )
```

This command is designed to perform the butterfly key expansion operation on an ECC private key in case of implicit and explicit certificates. Optionally the resulting public key is exported.

The result of the key expansion function  $f_k$  is calculated outside the HSM and passed as input. The expansion function is defined as  $f_k = f_{k\_int} \bmod I$ , where  $I$  is the order of the group of points on the curve.

User can call this function only after having opened a key management service flow.

Explicit certificates:

- $f_k$  = expansion function value

$out\_key = Key + f_k$

Implicit certificates:

- $f_k$  = expansion function value,
- hash = hash value used to in the derivation of the pseudonym ECC key,
- $pr_v$  = private reconstruction value

$out\_key = (Key + f_k) * hash + pr_v$

## Parameters

<i>args</i>	pointer to the structure containing the function arguments.

## Returns

error code
