3 General concepts related to the API

3.1 Session

The API must be initialized by a potential requestor by opening a session.

The session establishes a route (MU, DomainID...) between the requestor and the HSM. When a session is opened, the HSM returns a handle identifying the session to the requestor.

3.2 Service flow

For a given category of services, the requestor is expected to open a service flow by invoking the appropriate HSM API.

The session handle, as well as the control data needed for the service flow, are provided as parameters of the call. Upon reception of the open request, the HSM allocates a context in which the session handle, as well as the provided control parameters are stored and return a handle identifying the service flow.

The context is preserved until the service flow, or the session, are closed by the user and it is used by the HSM to proceed with the sub-sequent operations requested by the user on the service flow.

3.3 Example

```

/* Open a session: create a route between the user and the HSM */
hsm_open_session(&open_session_args, &session_hdl);

/* Open a key store - user is authenticated */
hsm_open_key_store_service(session_hdl, &open_svc_key_store_args, &key_store_hdl);
/* Open hash service - it grants access to hashing operations */
hsm_open_hash_service (session_hdl, &open_svc_hash_args, &hash_hdl);
/* Open cipher service - it grants access to ciphering operations */
hsm_open_cipher_service(key_store_hdl, &open_svc_cipher_args, &cipher_hdl);

/* Perform AES ECB, CCB ... */
hsm_cipher_one_go (cipher_hdl, &op_cipher_one_go_args);
/* Perform authenticate and encryption algos: e.g AES GCM */
hsm_auth_enc (cipher_hdl, &op_auth_enc_args);
/* Perform hashing operations: e.g SHA */
hsm_hash_one_go (hash_hdl, &op_hash_one_go_args);

/* Close the session and all the related services */
hsm_close_session(session_hdl);

```

3.4 Key store

A key store can be created by specifying the CREATE flag in the hsm_open_key_store_service API. Please note that the created key store will be not stored in the NVM till a key is generated/imported specifying the "STRICT OPERATION" flag.

Only symmetric and private keys are stored into the key store. Public keys can be exported during the key pair generation operation or recalculated through the hsm_pub_key_recovery API.

Secret keys cannot be exported under any circumstances, while they can be imported in encrypted form.

3.4.1 Key management

Keys are divided in groups, keys belonging to the same group are written/read from the NVM as a monolithic block. Up to 3 key groups can be handled in the HSM local memory (those immediately available to perform crypto operation), while up to 1000 key groups can be handled in the external NVM and imported in the local memory as needed. If the local memory is full (3 key groups already reside in the HSM local memory) and a new key group is needed by an incoming user request, the HSM swaps one of the local key group with the one needed by the user request. The user can control which key group must be kept in the local memory (cached) through the manage_key_group API lock/unlock mechanism.

As general concept, frequently used keys should be kept, when possible, in the same key group and locked in the local memory for performance optimization.

3.4.2 NVM writing

All the APIs modifying the content of the key store (key generation, key_management, key derivation functions) provide a "STRICT OPERATION" flag. If the flag is set, the HSM triggers and export of the encrypted key group into the external NVM and increments (blows one bit) the OTP monotonic counter used as roll back protection. Please note that the "STRICT OPERATION" has effect only on the current key group.

Any update to the key store must be considered as effective only after an operation specifying the flag "STRICT OPERATION" is acknowledged by the HSM. All the operations not specifying the "STRICT OPERATION" flags impact the HSM local memory only and will be lost in case of system reset

Due to the limited monotonic counter size (QXPB0 up to 1620 update available by default), the user should, when possible, perform multiple updates before setting the "STRICT OPERATION" flag (i.e. keys to be updated should be kept in the same key group).

Once the monotonic counter is completely blown a warning is returned on each update operation to inform the user that the new updates are not roll-back protected.

3.5 implementation specificities

HSM API is supported on different versions of the i.MX8 family. The API description below is the same for all of them but some features may not be available on some chips. The details of the supported features per chip can be found here:

- for i.MX8QXP: [i.MX8QXP specificities](#)

5.2.1 Detailed Description

The API must be initialized by a potential requestor by opening a session. Once a session is closed all the associated service flows are closed by the HSM.

5.2.2 Data Structure Documentation

5.2.2.1 struct open_session_args_t

Data Fields

| | | |

5.3 Key store

- struct [open_svc_key_store_args_t](#)

Macros

- #define [HSM_SVC_KEY_STORE_FLAGS_CREATE](#) ((hsm_svc_key_store_flags_t)(1u << 0))
It must be specified to create a new key store. The key store will be stored in the NVM only once a key is generated/imported specifying the STRICT OPERATION flag.

Typedefs

- typedef uint8_t [hsm_svc_key_store_flags_t](#)

Functions

- [hsm_err_t hsm_open_key_store_service](#) (hsm_hdl_t session_hdl, [open_svc_key_store_args_t](#) *args, hsm_hdl_t *key_store_hdl)
- [hsm_err_t hsm_close_key_store_service](#) (hsm_hdl_t key_store_hdl)

5.3.1 Detailed Description

User must open a key store service flow in order to perform the following operations:

- create a new key store
- perform operations involving keys stored in the key store (ciphering, signature generation...)
- perform a key store reprovisioning using a signed message. A key store re-provisioning results in erasing all the key stores handled by the HSM.

To grant access to the key store, the caller is authenticated against the domain ID (DID) and Messaging Unit used at the keystore creation, additionally an authentication nonce can be provided.

Data Fields

5.3.2 Data Structure Documentation

5.3.2.1 struct open_svc_key_store_args_t

Data Fields

| | | |
|---------------------------|----------------------|---|
| uint32_t | key_store_identifier | user defined id identifying the key store. Only one key store service can be opened on a given key_store_identifier. |
| uint32_t | authentication_nonce | user defined nonce used as authentication proof for accessing the key store. |
| uint16_t | max_updates_number | maximum number of updates authorized for the key store. Valid only for create operation. This parameter has the goal to limit the occupation of the monotonic counter used as anti-rollback protection. If the maximum number of updates is reached, HSM still allows key store updates but without updating the monotonic counter giving the opportunity for rollback attacks. |
| hsm_svc_key_store_flags_t | flags | bitmap specifying the services properties. |
| uint8_t | reserved | |
| uint8_t * | signed_message | pointer to signed_message to be sent only in case of key store re-provisioning |
| uint16_t | signed_msg_size | size of the signed_message to be sent only in case of key store re-provisioning |
| uint8_t | reserved_1[2] | |

5.3.3 Function Documentation

    hsm_hdl_t session_hdl,
    open_svc_key_store_args_t * args,
    hsm_hdl_t * key_store_hdl )
```

Open a service flow on the specified key store. Only one key store service can be opened on a given key store.

Parameters

| | |
|----------------------|---|
| <i>session_hdl</i> | pointer to the handle identifying the current session. |
| <i>args</i> | pointer to the structure containing the function arguments. |
| <i>key_store_hdl</i> | pointer to where the key store service flow handle must be written. |

Returns

`error_code` error code.

5.3.3.2 hsm_close_key_store_service()

```
hsm_err_t hsm_close_key_store_service (  
    hsm_hdl_t key_store_hdl )
```

Close a previously opened key store service flow. The key store is deleted from the HSM local memory, any update not written in the NVM is lost

Parameters

| | |
|---------------|--|
| <i>handle</i> | identifying the key store service flow to be closed. |
|---------------|--|

Returns

`error_code` error code.

User can replace an existing key only by generating a key with the same type of the original one.
- `#define HSM_OP_KEY_GENERATION_FLAGS_CREATE ((hsm_op_key_gen_flags_t)(1u << 1))`
Create a new key.
- `#define HSM_OP_KEY_GENERATION_FLAGS_STRICT_OPERATION ((hsm_op_key_gen_flags_t)(1u << 7))`

When set, the key is permanent (write locked). Once created, it will not be possible to update or delete the key anymore. Transient keys will be anyway deleted after a PoR or when the corresponding key store service flow is closed. This bit can never be reset.
- `#define HSM_KEY_INFO_TRANSIENT ((hsm_key_info_t)(1u << 1))`
Transient keys are deleted when the corresponding key store service flow is closed or after a PoR. Transient keys cannot be in the same key group than persistent keys.

5.4.3 Function Documentation

5.4.3.1 hsm_open_key_management_service()

```
hsm_err_t hsm_open_key_management_service (
    hsm_hdl_t key_store_hdl,
    open_svc_key_management_args_t * args,
    hsm_hdl_t * key_management_hdl )
```

Open a key management service flow

User must open this service flow in order to perform operation on the key store keys (generate, update, delete)

Parameters

| | |
|---------------------------|--|
| <i>key_store_hdl</i> | handle identifying the key store service flow. |
| <i>args</i> | pointer to the structure containing the function arguments. |
| <i>key_management_hdl</i> | pointer to where the key management service flow handle must be written. |

Returns

`error_code` error code.

5.4.3.2 hsm_generate_key()

```
hsm_err_t hsm_generate_key (
    hsm_hdl_t key_management_hdl,
    op_generate_key_args_t * args )
```

Generate a key or a key pair. Only the confidential keys (symmetric and private keys) are stored in the internal key store, while the non-confidential keys (public key) are exported.

The generated key can be stored using a new or existing key identifier with the restriction that an existing key can be replaced only by a key of the same type.

User can call this function only after having opened a key management service flow.

Parameters

| | |
|---------------------------------|---|
| <code>key_management_hdl</code> | handle identifying the key management service flow. |
| <code>args</code> | pointer to the structure containing the function arguments. |

Returns

error code

5.4.3.3 hsm_manage_key()

```
hsm_err_t hsm_manage_key (
    hsm_hdl_t key_management_hdl,
    op_manage_key_args_t * args )
```

This command is designed to perform the following operations:

- import a key creating a new key identifier (import and create)
- import a key using an existing key identifier (import and update)
- delete an existing key

The key encryption key (KEK) can be previously pre-shared or stored in the key store.

The key to be imported must be encrypted by using the KEK as following:

- Algorithm: AES GCM
- Key: root KEK
- AAD = 0
- IV = 12 bytes
- Tag = 16 bytes
- Plaintext: key to be imported

User can call this function only after having opened a key management service flow

Parameters

| | |
|---------------------------|---|
| <i>key_management_hdl</i> | handle identifying the key management service flow. |
| <i>args</i> | pointer to the structure containing the function arguments. |

Returns

error code

5.4.3.4 hsm_manage_key_group()

```
hsm_err_t hsm_manage_key_group (
    hsm_hdl_t key_management_hdl,
    op_manage_key_group_args_t * args )
```

This command is designed to perform the following operations:

- lock/unlock down a key group in the HSM local memory so that the keys are available to the HSM without additional latency
- un-lock a key group. HSM may export the key group into the external NVM to free up local memory as needed
- delete an existing key group

User can call this function only after having opened a key management service flow.

Parameters

| | |
|---------------------------|---|
| <i>key_management_hdl</i> | handle identifying the key management service flow. |
| <i>args</i> | pointer to the structure containing the function arguments. |

Returns

error code

5.4.3.5 hsm_butterfly_key_expansion()

```
hsm_err_t hsm_butterfly_key_expansion (
    hsm_hdl_t key_management_hdl,
    op_butt_key_exp_args_t * args )
```

This command is designed to perform the butterfly key expansion operation on an ECC private key in case of implicit and explicit certificates. Optionally the resulting public key is exported.

The result of the key expansion function f_k is calculated outside the HSM and passed as input. The expansion function is defined as $f_k = f_{k_int} \bmod l$, where l is the order of the group of points on the curve.

User can call this function only after having opened a key management service flow.

Explicit certificates:

- f_k = expansion function value

$out_key = Key + f_k$

Implicit certificates:

- f_k = expansion function value,
- $hash$ = hash value used in the derivation of the pseudonym ECC key,
- pr_v = private reconstruction value

$out_key = (Key + f_k) * hash + pr_v$

Parameters

| | |
|---------------------------|---|
| <i>key_management_hdl</i> | handle identifying the key store management service flow. |
| <i>args</i> | pointer to the structure containing the function arguments. |

Parameters

| | |
|---------------------------|---|
| <i>key_management_hdl</i> | handle identifying the key management service flow. |
|---------------------------|---|

Returns

error code

- `#define HSM_OP_KEY_EXCHANGE_FLAGS_USE_EPHEMERAL ((hsm_op_key_exchange_flags_t)(1u << 2))`
Use an ephemeral key (freshly generated key)
- `#define HSM_OP_KEY_EXCHANGE_FLAGS_STRICT_OPERATION ((hsm_op_key_exchange_flags_t)(1u << 7))`
The request is completed only when the new key has been written in the NVM. This applicable for persistent key only.

5.21.3 Function Documentation

5.21.3.1 hsm_key_exchange()

```
hsm_err_t hsm_key_exchange (
    hsm_hdl_t key_management_hdl,
    op_key_exchange_args_t * args )
```

This command is designed to derive a secret key that will be stored in the key store as a new key or as an update of an existing key. For this secret key derivation, we can use, as input, a freshly generated key or an existing key from the key store. User can call this function only after having opened a key management service flow

Parameters

| | |
|---------------------------|---|
| <i>key_management_hdl</i> | handle identifying the key store management service flow. |
| <i>args</i> | pointer to the structure containing the function arguments. |
